

MULTIPURPOSE FLOW CONTROL DEVICE

1. CROSS REFERENCE TO RELATED APPLICATIONS

The present application is a continuation-in-part application and claims the
5 benefit of a co-pending non-provisional patent application, entitled "Multipurpose Flow
Control Device," that was filed on June 16, 2003, and assigned Serial No. 10/462,442, which
was a continuation-in-part and claimed the benefit of a non-provisional patent application,
entitled "Pet Drinking Aid Device," that was filed on June 24, 2002, and assigned Serial No.
10/178,606. The entire contents of both of the foregoing non-provisional patent applications
10 are incorporated by reference herein.

2. TECHNICAL FIELD.

The present disclosure relates to a device for use with a container or vessel containing
a fluid, and more particularly to a device for use with a bottle to assist in dispensing such fluid
in a controlled manner, e.g., to assist an animal in drinking therefrom. The present disclosure
15 further relates to a container and/or vessel that includes an advantageous flow regulation
device.

3. BACKGROUND OF THE DISCLOSURE

Fluids are routinely contained within containers and/or vessels, e.g., plastic and/or
glass bottles. To gain access to the fluids contained with a container/vessel, a cap is generally
20 removed and the fluid is poured or otherwise dispensed therefrom. Thus, for example, in the
case of plastic beverage bottles, a cap is generally screw threaded onto the throat of the bottle

which can be removed, as desired, when it is desired to access the contents thereof. The beverage is generally consumed directly from the bottle, by way of a straw, or by pouring the beverage into a cup or glass.

In certain circumstances, beverage/water bottles may be provided with a control
5 mechanism that permits fluid to flow therefrom upon axial movement of an annular flange relative to a fixed central abutment member. By moving the annular flange away from the bottle, an annular fluid flow path around the central abutment member is created. Axial movement of the annular flange is generally limited by a stop mechanism, thereby ensuring that the annular flange does not become separated from the bottle/control mechanism. Once
10 the control mechanism is in the “open” position, fluid may be dispensed from the bottle under the action of gravity by tilting or inverting the bottle in combination with squeezing and/or suction forces. Return movement of the annular flange toward the bottle may be undertaken to “close” the bottle, i.e., prevent further fluid flow therefrom.

The foregoing bottle designs are generally effective for human consumption of fluids.
15 However, such designs are not effective for a host of other applications. Thus, for example, pet owners involved in providing their pets with recreation encounter a variety of issues. For example, dog owners encounter issues associated with satisfying a dog’s thirst when dog and owner are away from the dog’s water bowl, e.g., when on a walk or engaged in athletic/recreational activities. It is often inconvenient and/or impractical when not at home to
20 bring along and set up a bowl or some other container from which a pet can drink. While naturally occurring sources of fluid refreshment are sometimes available, e.g., ponds, puddles

and the like, more frequently pet owners are left to their own ingenuity in attempting to address their dog's thirst when remote from the home-based water bowl.

Efforts have been devoted in the prior art to developing devices and/or systems for providing fluid refreshment to pets. For example, significant efforts have been expended in providing fluid dispensers for caged pets, such as rabbits, guinea pigs, hamsters and the like. U.S. Patent No. 3,529,575 to Schalk et al., U.S. Patent No. 3,771,496 to Atchley, and U.S. Patent No. 5,363,802 to Huff disclose drinking bottles that may be detachably mounted to a pet's cage. The fluids from the disclosed drinking bottles are introduced into the cage by way of an angled tube that fits through openings defined in the wire cage. Control and/or regulation of fluid flow into the cage is provided by a displaceable ball (Atchley '496 patent and Huff '802 patent), a valve assembly (Schalk '575 patent), or multiple balls operating in conjunction to establish a seal.

Prior art efforts have also been devoted to developing systems for use by larger pets, e.g., dogs. For example, U.S. Patent No. 5,301,634 to Ho discloses an animal feeder designed for convenient mounting to a horizontal wire member, the feeder including a ball 60 disposed in a tubular extension 43.

A pet drinking device offering portability to pet owners is disclosed in U.S. Patent No. 6,293,226 to Hwang. The device of the Hwang '226 patent includes a bottle having a threaded mouth and a cover that engages the threaded mouth. An unsecured gasket is positioned between the cover and the bottle. The cover includes a main body that is internally threaded to engage the mouth of the bottle, and a tube. The tube defines an outwardly threaded portion at an end thereof. An internally threaded sleeve is mounted to the outwardly

threaded portion of the tube. An unsecured sealing ring is positioned between the tube and the sleeve. A ball and washer are positioned within the sleeve and a lid is tethered to the cover. A belt is also provided for mounting the Hwang drinking device to a stationary structure, e.g., a hook on a wall.

5 Despite the prior art efforts referenced hereinabove, a need remains for advantageous control mechanisms for regulating the flow of fluid from a container or vessel. More specifically, a need exists for a drinking aid for use with animals/pets, e.g., dogs, cats, ferrets, rodents and the like, that may be readily utilized with a container, e.g., a conventional water/beverage bottle, and that offers the animal/pet convenient and controlled access to fluid
10 refreshment.

4. SUMMARY OF THE DISCLOSURE

The present disclosure is directed to a control mechanism for regulating the flow of fluid from a container or vessel, e.g., a plastic bottle containing a fluid such as water or the like. The disclosed control mechanism may be advantageously employed in a variety of
15 applications where it is desired to dispense and/or access fluids in a controlled manner, e.g., applications wherein a liquid, colloidal system, suspension or the like is to be dispensed/accessed in a controlled manner. The disclosed control mechanism may be provided as an accessory item, i.e., an item that is adapted to be secured to a container/vessel/bottle. The disclosed control mechanism may also be pre-mounted to a
20 container/vessel/bottle, e.g., in the manufacturing process. In such circumstance, the present disclosure is directed to the container/vessel/bottle in combination with such advantageous control mechanism.

In an exemplary embodiment, the present disclosure relates to an animal or pet drinking aid that provides animals/pets with convenient and controlled access to fluid refreshment, e.g., when away from a home-based water bowl. The disclosed drinking aid overcomes difficulties associated with typical water bottles that deliver uncontrolled fluid flow when fully or partially inverted. The uncontrolled fluid flow provided by such conventional water bottles often finds its way into a pet's windpipe or onto the ground, regardless of the effort and care expended in attempting to address the pet's thirst.

In an exemplary embodiment, the disclosed pet drinking aid generally includes a cap that is adapted to be detachably mounted to a fluid-containing bottle. The cap may be advantageously threaded onto a fluid-containing bottle. Alternatively, the disclosed cap may include an elastomeric sleeve that facilitates detachably mounting the cap to a bottle, thereby obviating the need for cooperative threads as between the cap and the bottle. The disclosed cap also includes an internal ball that advantageously restricts and/or moderates the flow of fluid from a bottle when positioned at various angles of inversion. The internal ball is typically restrained or captured within the cap by a circumferential flange or rim that advantageously includes an elastomeric, e.g., rubber, washer adjacent and/or in engagement therewith. The washer provides an enhanced fluid seal when a pet is not accessing fluid contained within the container. Thus, for example, the bottle may generally be inverted without fluid leakage due to sealing interaction between the ball and the elastomeric washer, and between the washer and the rim of the cap.

In a first preferred embodiment of the pet drinking aid of the present disclosure, a ball is captured within a cap and is resiliently biased toward the dispensing end of the cap, e.g., by

a compression spring. The cap is adapted to be detachably mounted to a fluid-containing bottle, e.g., a conventional water bottle. Preferably, the cap is internally threaded so as to facilitate screwing the cap onto the outwardly threaded neck of the bottle. In an exemplary embodiment of the disclosed pet drinking aid, a ball for regulating fluid flow and an internal plastic spring are positioned within the cap. The plastic spring advantageously supplies a light force against the ball so as to bias the “floating” ball against a lip or flange formed at or near the dispensing end of the cap, thereby capturing the ball therewithin. The diameter of the compression spring is generally slightly less than the diameter of the ball where it contacts the ball, thereby ensuring that the spring maintains engagement with the ball, i.e., the ball is not able to pass through the center of the spring. At the opposite end, the base of the spring typically engages a ridge formed in or defined by the cap, and may be advantageously staked, glued or otherwise mounted to the cap. Alternatively, the base of spring may be positioned between and secured relative to spaced ridges formed in the cap, or positioned between and secured relative to a plurality of spaced, inwardly projecting guides and/or projections formed in the cap. In a preferred embodiment of the present disclosure, the ridge is positioned at or near the midpoint of the cap.

Once the cap is mounted to a fluid-containing bottle according to preferred embodiments of the present disclosure, and the bottle is fully or partially inverted, the motion/pressure supplied to the ball by the pet’s tongue, e.g., when licking the bottle/cap, pushes the ball in slightly, i.e., against the bias of the spring positioned therebehind. The movement of the ball relative to the housing of the cap allows fluid within the bottle to flow around the ball. Thus, as the pet licks the ball, the ball assumes a slightly recessed position

within the cap and simultaneously spins/rotates, thereby allowing fluid to continuously flow to the pet's mouth. When the pet's licking action ceases, the spring advantageously biases the ball back into sealing engagement with the washer positioned adjacent the rim of the cap, thereby discontinuing the flow of fluid to the pet, regardless of the orientation of the bottle.

5 According to further preferred embodiments of the present disclosure, small projections/guides or a continuous lip or ridge may be provided on the interior of the cap to more reliably secure the elastomeric washer in position. This structural arrangement advantageously prevents the washer from becoming dislodged and interfering with the ball's desired motion. In exemplary embodiments of the disclosed pet drinking aid, four
10 guides/projections are provided to secure the washer in position. The length of the guides/projections is selected so as to ensure a desired level of security while simultaneously permitting facile assembly of the device. Thus, for example, the guides/projections may be fabricated such that they are about half the thickness of the washer material, and the guides/projections may be circumferentially spaced around the interior of the cap, e.g., one
15 guide/projection located at 0 degrees, one at 90 degrees, one at 180 degrees and one at 270 degrees. Alternatively, according to a further exemplary embodiment of the present disclosure, one continuous lip or ridge may be substituted for individual, spaced guides/projections. According to such alternative embodiment, the lip may be advantageously fabricated such that its thickness is less than the thickness of the washer. The thickness of the
20 securing structure (e.g., guides/projections or lip/ridge) is selected so as not to impede/interfere with the ball sealing against the washer.

Several forces cooperate or interact to control/moderate the flow of fluid from a bottle/cap according to a spring-biased embodiment of the present disclosure. For example, the spring bias and the fluid pressure associated with the inversion (full or partial) of the bottle generally acts against the force of the pet's tongue to determine the degree to which fluid flows from the bottle. Moreover, the speed with which the ball is rotated by the pet's tongue influences the fluid dispensing rate and/or volume. The incremental force supplied by the spring bias advantageously provides a tighter seal to the cap of the present disclosure, particularly in circumstances where the bottle is positioned upright. That is, the spring continuously provides force for the ball to contact the washer at the cap's outer opening, even when the bottle is upright, thereby minimizing or avoiding inadvertent leaking. However, the force of the spring is selected such that it is not so strong as to prevent the pet's drinking motion from pressing the ball slightly inward and moving it in a circuitous motion, thereby allowing fluid to flow to the pet.

According to a further preferred embodiment of the present disclosure, an alternative cap is provided that includes an internal ball captured therewithin and a washer mounted at or adjacent the top of the cap. Unlike the previously described embodiments, however, this further preferred embodiment omits a biasing spring. A ridge is formed on the internal surface of the cap and defines the position where the ball rests when the cap and bottle are upright. Another washer may be optionally provided between the ball and the internal ridge to enhance sealing therebetween. The optional washer is advantageously secured relative to the cap by a plurality of small projections/guides or a continuous lip or ridge, as described with reference to the first washer hereinabove.

Inclusion of the second washer advantageously provides an enhanced seal when the fluid-containing bottle is upright. Generally, the inclusion of the optional washer necessitates slightly greater space for ball movement, so that when the pet is drinking from the bottle and cap, the ball is not pushed so far inward that it is forced into engagement with the additional washer. If insufficient space is provided, smooth rolling of the ball is impeded and fluid flow unacceptably retarded. It is noteworthy, however, that inclusion of an additional washer is generally not necessary or feasible in embodiments that utilize a biasing spring, as described hereinabove, because the ball may be prevented from engaging the second washer by the interposition of the spring.

In a further exemplary embodiment, a control mechanism is disclosed for use with a vessel/container/bottle and includes a lower cap member, overcap member and a ball that is captured therebetween. The lower cap member is adapted to be mounted to a vessel, container or bottle, e.g., by screw threading or the like. The overcap member is adapted to be movably mounted relative to the lower cap, e.g., by threading engagement therewith. The ball typically rests on an internal flange or shelf formed in the lower cap member and, depending on the relative location of the overcap member, either prevents fluid from flowing through the control mechanism or permits fluid to flow therearound in a regulated fashion.

More particularly, in an exemplary embodiment of the disclosed control mechanism, the overcap member may be “tightened” such that the ball is prevented from movement relative to the lower cap/overcap members, thereby preventing fluid flow therearound. By moving the overcap member away from the lower cap member, the ball is freed up for rotational and axial (and limited lateral) motion within the space defined between the lower

cap/overcap members, thereby permitting fluid flow from the vessel/container/bottle and through an opening defined in the overcap member. Exemplary control mechanisms may include further advantageous features and functionalities, e.g., reference indicator(s) that reflect (e.g., on a relative basis) the degree to which fluid will flow therethrough, detent mechanisms for audibly and/or tactilely communicating the degree to which the control mechanism has been opened/closed, and/or a backflow mechanism to prevent fluid from returning to the vessel/container/bottle from the control mechanism. Additional features, functionalities and applications of exemplary control mechanisms according to the present disclosure are set forth in the detailed description which follows.

In a further exemplary embodiment of the present disclosure, the upper cap includes an angularly oriented portion that facilitates use thereof. The upper cap may be fabricated from two distinct elements and may advantageously capture a pair of balls therewith that cooperate to control fluid flow therethrough. The balls are typically in tangential contact, such that relative movement of a first ball translates to corresponding motion of the second ball. The angular portion may be oriented at a variety of angles relative to the axis of the device, e.g., an angle of 30° to 60° relative to the axis of the device, and preferably on the order of 45°. Rotational movement of the upper cap relative to a lower cap advantageously opens/closes the fluid control mechanism for passage of fluid therethrough.

According to preferred embodiments of the present disclosure, the advantageous control mechanism and animal/pet drinking aid are fabricated from conventional materials of construction, e.g., plastic(s), rubber(s) and the like. The disclosed control mechanism and pet drinking aid are advantageously sized and dimensioned to be utilized with any standard size

fluid bottle, as are known in the art. In addition, the size and dimensions of the disclosed control mechanism and animal/pet drinking aid may be modified, based on the teachings herein, to effectively interact with alternative and/or future fluid containers.

Control mechanisms and animal/pet drinking aids according to the present disclosure
5 are relatively inexpensive to fabricate and provide an efficient, safe and reliable way to dispense fluids from a container/vessel/bottle and/or provide animals/pets with fluids from a bottle, particularly in instances and places where a bowl or other container is simply not a feasible or convenient choice. Thus, according to the present disclosure, a control mechanism and an animal/pet drinking aid are provided that allow users to avoid undesirable situations
10 where the pet may gag or choke on fluids supplied from a typical water bottle. The disclosed control mechanism and animal/pet drinking aid advantageously overcome the potential for waste and spillage generally associated with fluids provided from containers/vessels/bottles, e.g., fluids provided to pets in portable water bowls and the like. Additional features, benefits and functionalities associated with control mechanisms and animal/pet drinking aids
15 according to the present disclosure will be apparent from the detailed description which follows.

5. BRIEF DESCRIPTION OF THE FIGURES

The features, benefits and functionalities of the present disclosure will become more readily apparent to those skilled in the art from the following detailed description of preferred
20 embodiment(s) when considered together with the accompanying drawings, wherein:

6. DETAILED DESCRIPTION OF PREFERRED EMBODIMENT(S)

15 The control mechanisms of the present disclosure advantageously regulate fluid flow from a container, vessel or bottle. The control mechanism may be provided as a free standing item, e.g., an accessory for independent purchase and use, or as part of an integrated product offering, e.g., permanently or detachably secured to a container, vessel or bottle. The disclosed control mechanisms may be employed in a variety of applications, e.g., to moderate
20 and/or regulate flow of liquids, colloidal systems, suspensions and the like. For example, control mechanisms according to the present disclosure may be employed in systems wherein

the fluid is to be consumed and in systems wherein the fluid is to be applied to a surface or substrate, e.g., deodorants/anti-perspirants, fluid application systems such as wetting devices for mailing applications, colorant dispensers, inking mechanisms and the like. Thus, the disclosed control mechanisms may be employed in any application where it is desired to regulate the flow of a fluid's egress from a container, vessel or bottle.

In an exemplary application of the present disclosure, the control mechanisms may be employed in connection with an animal or pet drinking aid. The animal/pet drinking aids of the present disclosure provide pets, e.g., dogs, cats, ferrets, rodents and the like, with convenient and controlled access to fluid refreshment, e.g., when away from a home-based water bowl. As discussed in greater detail below, the disclosed animal/pet drinking aids overcome difficulties associated with typical water bottles that deliver uncontrolled fluid flow when fully or partially inverted. The uncontrolled fluid flow provided by such conventional water bottles often finds its way into a pet's windpipe or onto the ground, regardless of the effort and care expended in attempting to address the pet's thirst. The disclosed animal/pet drinking aids are advantageously sized and dimensioned to be utilized with any standard size fluid bottle, as are known in the art. Adjustments to the size and/or dimensions of the disclosed animal/pet drinking aids may be made to facilitate use with non-conventionally sized fluid bottles, as is apparent from the detailed description provided herein.

Although the exemplary control mechanisms of Figures 1-5 are referred to as pet drinking aids, it is to be understood that such devices/structures may be employed in a variety of applications, e.g., in systems wherein a fluid is to be consumed and/or in systems wherein a fluid is to be applied to a surface or substrate, as noted above. Accordingly, the exemplary pet

drinking aids described hereinafter are illustrative of control mechanisms having a host of advantageous applications, including without limitation, as pet drinking aids.

With reference to Figures 1 and 2, a first exemplary pet drinking aid 100 according to the present disclosure is depicted in conjunction with a conventional bottle 50. The bottle 50 includes a neck 52 that defines outwardly threaded portion 54. Two spaced, circumferential ridges 56, 58 are also defined on the outside of neck 52. Ridges 56, 58 are conventional in nature, and generally function to provide tamper resistance to bottle 50 through interaction with a conventional cap (not shown), as is known in the art.

Pet drinking aid 100 includes a cylindrical cap 102 that defines an axial passage 103 and inwardly directed threads 104 at a first end thereof. Inwardly directed threads function as exemplary means for detachably securing pet drinking aid 100 to bottle 50 according to the present disclosure. The thread pitch and spacing of inwardly directed threads 104 are generally selected so as to cooperate with conventional drinking fluid containers/bottles, e.g., bottled water and/or soda containers. Cylindrical cap 102 is generally fabricated from conventional plastic materials, as are known in the art.

An inwardly directed, circumferential flange or rim 108 is defined at an opposite end of cap 102. Flange 108 is typically integrally formed with cap 102, although a cooperating flange structure may be joined to cylindrical cap 102, if so desired. Flange 108 provides an abutment surface for positioning a washer 110 within the passage defined by cap 102. Washer 110 provides an enhanced fluid seal when a pet is not accessing fluid contained within the bottle 50, as discussed in greater detail below. Washer 110 is fabricated from conventional elastomeric materials, e.g., rubber, to facilitate the sealing function performed thereby.

A continuous, circumferential lip or ridge 112 is advantageously formed on the interior surface of cap 102 in spaced relation relative to flange 108. Circumferential lip 112 functions in cooperation with flange 108 to more reliably secure washer 110 in position within cap 102. Lip 112 is generally fabricated such that its thickness is less than the thickness of washer 110.

5 The thickness of circumferential lip 112 is selected so as not to impede/interfere with ball 114 (discussed below) sealing against washer 110.

In alternative embodiments of the present disclosure, a plurality of guides and/or projections may be provided in lieu of circumferential lip 112 to reliably secure washer 110 in position. In such alternative embodiments, the length of the guides/projections is selected so
10 as to ensure a desired level of security while simultaneously permitting facile assembly of the device. The thickness of the guides/projections is generally selected so as not to impede/interfere with sealing interaction between washer 110 and ball 114. Thus, for example, the guides/projections may be fabricated such that they are about half the thickness of washer 110, and the guides/projections may be circumferentially spaced around the interior
15 of cap 102, e.g., one guide/projection located at 0 degrees, one at 90 degrees, one at 180 degrees and one at 270 degrees.

A second washer 106 is generally provided at a predefined distance from the first end of cylindrical cap 102, i.e., from washer 110 and flange 108. Second washer 106 is typically secured in place by structural features formed on the inside surface of cap 102, e.g., between
20 first and second securing flanges 106a, 106b. Second washer 106 is fabricated from the same types of materials as washer 110, and may be identical in all respects to washer 110. The spacing between washer 110 and second washer 106 is selected so as to permit movement of

ball 114, as discussed herein below. In a preferred embodiment of the present disclosure, second washer 106 is located at a position intermediate the first and second ends of cap 102 and axial passage 103, and in a particularly preferred embodiment, second washer 106 is positioned substantially at or near the midpoint of axial passage 103.

5 With further reference to Figure 1, a ball 114 is positioned for movement within axial passage 103. Ball 114 is generally spherical in shape and fabricated from a substantially non-deformable material, e.g., rubber or a hard plastic. Ball 114 is captured within axial passage 103 by washer 110 and second washer 106, i.e., removal of ball 114 from cap 102 is prevented by the diameters of the passages through washer 110 and second washer 106. The
10 diameter of ball 114 is thus characterized in that it is less than the diameter of inner passage 103, but greater than the diameter of the openings formed in washer 110 and second washer 106.

 Based on the manner in which ball 114 is captured within axial passage 103, ball 114 is capable of rotatable movement and limited axial movement relative to cap 102. As shown
15 in Figure 1, bottle 50 and cap 102 are shown fully inverted, such that fluid within bottle 50 flows into axial passage 103 and bears against ball 114. Ball 114 engages washer 110 and forms a seal therewith. Thus, in the absence of movement of ball 114 relative to washer 110, i.e., rotatable and/or axial movement of ball 114, fluid is prevented from exiting axial passage 103 through flange 108. Thus, bottle 50 may be inverted without fluid leakage due to sealing
20 interaction between ball 114 and the washer 110.

 With bottle 50 fully or partially inverted, if a pet licks the exposed portion of ball 114, the motion and pressure from the pet's tongue pushes the ball in slightly, i.e., against the

downward pressure of the fluid within axial passage 103, and generally causes rotational motion of ball 114 relative to cap 102. The movement of ball 114 (rotational and/or axial) relative to cap 102 allows fluid within the bottle to flow around the ball. Thus, as the pet licks ball 114, the ball assumes a recessed position within axial passage 103 of cap 102 relative to the sealing orientation depicted in Figure 1, and simultaneously spins/rotates, thereby allowing fluid to continuously flow to the pet's mouth.

When the pet's licking action ceases (and assuming bottle 50 remains in an inverted or slightly inverted orientation), ball 114 returns to its position of sealing engagement with washer 110, e.g., under the continued downward force of fluid contained within axial passage, thereby discontinuing the flow of fluid to the pet. When bottle 50 is rotated to a non-inverted orientation, the downward force on ball 114 supplied by fluid within axial passage 103 (and gravity) is removed. In the absence of such downward force, ball 114 reorients itself within axial passage 103 such that it engages second washer 106. The engagement between ball 114 and second washer 106 functions to substantially "close" bottle 50 when in the non-inverted orientation, thereby preventing significant, undesired fluid dispersal through cap 102.

With reference to Figure 2, an alternative embodiment of a pet drinking aid 200 is schematically depicted in cross section. Pet drinking aid 200 features many of the same structures and functions as are described herein above with reference to pet drinking aid 100 and, in the interest of clarity, the same numeric designations are employed for structures that are unchanged relative to pet drinking aid 100. Thus, for example, pet drinking aid 200 includes a cylindrical cap 202 that is detachably secured to a bottle 50 through helical threads

104. Cap 202 defines an axial passage 103 and a flange or rim 108 at an end opposite helical threads 104.

Washer 110 is positioned adjacent flange 108 and second washer 106 is positioned intermediate the first and second ends of cap 202. However, unlike cap 102 of pet drinking

5 aid 100, cap 202 includes a plurality of guides or projections 118a, 118b, 118c for securing washer 110 relative to cap 202. Three guides 118a, 118b, 118c are depicted in the cross

sectional view of Figure 2. However, a fourth guide/projection (not pictured) is positioned opposite guide 118b. Thus, according to a preferred embodiment of the present disclosure,

guides 118a, 118b, 118c and the unpictured guide are circumferentially spaced around the

10 interior surface of cap 202, i.e., spaced 90° from each other. Thus, a guide is advantageously

formed at 0°, 90°, 180° and 270°. The disclosed guides/projections are generally integrally

formed with cap 202, i.e., formed in connection with the conventional molding of cap 202.

With further reference to Figure 2, guides or projections 116a, 116b, 116c are provided in place of securing flange 106b. Guides 116a, 116b, 116c extend inwardly from the inner

15 surface of cap 202 and are preferably integrally formed with cap 202, e.g., during the molding of cap 202. A fourth, non-pictured guide is positioned opposite guide 116b.

The lengths of the guides/projections 116a, 116b, 116c and 118a, 118b, 118c schematically depicted in Figure 2 are generally selected so as to ensure a desired level of

security for washers 106 and 110, respectively, while simultaneously permitting facile

20 assembly of pet drinking aid 200. Thus, for example, the foregoing guides/projections may be

advantageously fabricated such that they are about half the thickness of the washer material.

In addition, the thickness of the guides/projections is selected so as not to impede/interfere with ball 114 sealing against washers 106, 110.

Turning to Figures 3 and 4, an alternative exemplary pet drinking aid embodiment of the present disclosure is depicted in which identical reference designations are used to identify structures that correspond to structures discussed with reference to the preceding
5 embodiments. Pet drinking aid 300 is depicted in conjunction with a conventional bottle 50 that includes a neck 52 having outwardly threaded portion 54. Pet drinking aid 300 includes a cylindrical cap 302 that defines an axial passage 303 and inwardly directed threads 304 at a first end thereof. Inwardly directed threads function as exemplary means for detachably
10 securing pet drinking aid 300 to bottle 50 according to the present disclosure. The thread pitch and spacing of inwardly directed threads 304 are generally selected so as to cooperate with conventional drinking fluid containers/bottles, e.g., bottled water and/or soda containers. Cylindrical cap 302 is generally fabricated from conventional plastic materials, as are known in the art.

15 An inwardly directed, circumferential flange or rim 308 is defined at an opposite end of cap 302. Flange 308 is typically integrally formed with cap 302, although a cooperating flange structure may be joined to cylindrical cap 302, if so desired. Flange 308 provides an abutment surface for positioning a washer 310 within the axial passage 303 defined by cap 302. Washer 310 provides an enhanced fluid seal when a pet is not accessing fluid contained
20 within the bottle 50, as discussed in greater detail below. Washer 310 is fabricated from conventional elastomeric materials, e.g., rubber, to facilitate the sealing function performed thereby. A continuous, circumferential lip or ridge 312 is formed on the interior surface of

cap 302 in spaced relation relative to flange 308 which functions in cooperation with flange 308 to more reliably secure washer 310 in position within cap 302. The thickness of circumferential lip 312 is selected so as not to impede/interfere with ball 314 sealing against washer 310.

5 A ball 314 is positioned for movement within axial passage 303 of cap 302. Ball 314 is generally spherical in shape and fabricated from a substantially non-deformable material, e.g., rubber or a hard plastic. A compression spring 320 is positioned within axial passage 303 and engages, i.e., contacts, ball 314 at one end thereof. At the other end, compression spring 320 is mounted relative to the inner surface of cap 302 with respect to ridge 322.

10 Spring 320 may be staked, glued or otherwise mounted to cap 302, or may be merely captured between a ridge and ball 314. In a preferred embodiment of the present disclosure, the ridge is positioned at or near the midpoint of cap 302. Alternatively, the base of spring 320 may be positioned between and secured relative to spaced ridges 322 formed in cap 302, or positioned between and secured relative to a plurality of spaced, inwardly projecting guides and/or
15 projections formed in the cap. In this latter embodiment, axially spaced sets of inwardly projecting guides and/or projections may be provided, e.g., at the axial locations of ridges 322 of Figure 4. As will be readily apparent to persons skilled in the art, each of such arrangements constitutes a means of mounting spring 320 relative to cap 302 for purposes of the present disclosure.

20 Ball 314 is thus captured within axial passage 303 between washer 310 and compression spring 320, and is resiliently biased toward the dispensing end of cap 302. The diameter of compression spring 320 is generally slightly less than the diameter of ball 314

where it contacts the ball, thereby ensuring that spring 320 maintains engagement with ball 314, i.e., the ball is not able to pass through the center of the spring. The removal of ball 314 from cap 302 is prevented by the diameter of the opening formed in washer 310 and the inner diameter of compression spring 320. The diameter of ball 314 is thus characterized in that it is less than the diameter of inner passage 103, but greater than the diameter of the openings formed in washer 310 and compression spring 320.

Compression spring 320 may be fabricated from a variety of materials, e.g., plastic, metal and the like. Alternatively, a hollow, biasing foam member may be substituted for compression spring 320 to bias ball 314 toward the dispensing end of cap 302. A

compression spring and hollow, biasing foam member are exemplary biasing means for biasing ball 314 toward inwardly directed flange 308. Of note, with reference to the cap embodiment of Figures 3 and 4, with the inclusion of compression spring 320, a washer is generally not included in juxtaposition to spaced ridges 322 (or inwardly projecting guides and/or projections). Nonetheless, it may be desirable to form ridges 322 (or the guides/projections) in cap 302, e.g., if a single mold is fabricated for the manufacture of caps that both include and do not include a compression spring. Moreover, the presence of ridges 322 (or the guides/projections) may facilitate the mounting of compression spring 322 relative to cap 302, as discussed herein above.

Several forces cooperate or interact to control/moderate the flow of fluid from a bottle/cap according to embodiments of the present disclosure that include a biasing means, e.g., a compression spring. For example, the spring bias and the fluid pressure associated with the inversion (full or partial) of the bottle generally acts against the force of the pet's tongue to

determine the degree to which fluid flows from the bottle. Moreover, the speed with which the ball is rotated by the pet's tongue influences the fluid dispensing rate and/or volume. The additional force supplied by the spring bias advantageously provides a tighter seal to the cap of the present disclosure, particularly in circumstances where the bottle is positioned upright.

5 That is, the spring continuously provides force for the ball to contact the washer at the cap's outer opening, even when the bottle is upright, thereby minimizing or avoiding inadvertent leaking. However, the force of the spring is selected such that it is not so strong as to prevent the pet's drinking motion from pressing the ball slightly inward and moving it in a circuitous motion, thereby allowing fluid to flow to the pet.

10 Once cap 302 is mounted to bottle 50 according to preferred embodiments of the present disclosure, and the bottle is fully or partially inverted, the motion/pressure supplied to ball 314 by the pet's tongue, e.g., when licking in the vicinity of flange 308, pushes ball 314 in slightly, i.e., against the bias of compression spring 320 positioned therebehind. The movement of ball 314 relative to cap 302 (rotatable and/or axial) allows fluid within the bottle
15 to flow around the ball. Thus, as the pet licks ball 314, the ball assumes a slightly recessed position within cap 302 and simultaneously spins/rotates, thereby allowing fluid to continuously flow to the pet's mouth. When the pet's licking action ceases, compression spring 320 advantageously biases ball 314 back into sealing engagement with washer 310 positioned adjacent the flange 308, thereby discontinuing the flow of fluid to the pet,
20 regardless of the orientation of bottle 50. When bottle 50 is rotated to a non-inverted orientation, the biasing force applied to ball 314 by compression spring 320 advantageously maintains the ball in sealing engagement with washer 310.

With reference to Figure 5, a further exemplary embodiment of the pet drinking aid of the present disclosure is depicted. Pet drinking aid 400 is similar in most respects to pet drinking aid 300 described herein above with reference to Figures 3 and 4. Thus, pet drinking aid 400 includes a compression spring 320 that biases ball 314 into engagement with washer 310 positioned adjacent flange 308. However, unlike pet drinking aid 300, the cap 402 of pet drinking aid 400 is detachably mounted to bottle 50 by way of an elastomeric sleeve 424 that advantageously fits over and resiliently engages neck 52 of bottle 50. Elastomeric sleeve 424 is secured to the cap 402 through appropriate mounting means, e.g., glue, a cooperative tongue and groove structure, and the like, and facilitates detachably mounting of cap 402 to a bottle, thereby obviating the need for cooperative threads as between the cap and the bottle. Elastomeric sleeve 424 may be fabricated from a host of elastomeric materials, e.g., rubber, elastomeric polymer or similar material as would be apparent to persons skilled in the art. The inner diameter of elastomeric sleeve 424 in its rest, i.e., non-stretched condition, is typically slightly less than the maximum diameter of the neck of the bottle to which it is to be secured. For purposes of diameter selection, the diameter of the bottle's neck is deemed include the threads and/or lip formed on the neck of the bottle. Thus, elastomeric sleeve 424 is sized and configured to stretch over the neck of a bottle and maintain a secure relationship therewith unless and until subsequently removed by the user.

The pet drinking aids of the present disclosure are relatively inexpensive to fabricate and provide an efficient, safe and reliable way to provide pets with fluids from a bottle, particularly in instances and places where a bowl or other container is simply not a feasible or convenient choice. Thus, according to the present disclosure, a pet drinking aid is provided

that allows users to avoid undesirable situations where the pet may gag or choke on fluids supplied from a typical water bottle. The disclosed pet drinking aid advantageously overcomes the potential for waste and spillage generally associated with fluids provided to pets in portable water bowls and the like.

5 Turning to Figures 6-10, an exemplary control mechanism 500 for use with a container, vessel and/or bottle is depicted. Control mechanism 500 may be used in a host of applications, including systems wherein a fluid is to be consumed, e.g., an animal/pet drinking aid, and systems wherein a fluid is to be applied to a surface or substrate, e.g., as part of a deodorant, anti-perspirant or other fluid dispensing apparatus and/or in wetting envelopes,
10 applying a colorant or adherent to a substrate, and the like. As will be apparent to persons skilled in the art, the disclosed control mechanism may be employed in any application where it is desired to control and/or regulate fluid flow from a container, vessel and/or bottle. Control mechanism 500 advantageously comprises only three structural elements: a lower cap member, an overcap and a ball.

15 With particular reference to Figures 6, 7 and 10, control mechanism 500 includes a lower cap member 502, an overcap member 504 and a ball 506. Control mechanism 500 is substantially cylindrical in shape, with a truncated, conical upper portion formed by overcap member 504. The diameter of control mechanism 500 is generally defined based on the size and/or dimensions of the neck of the container, vessel or bottle with which it is intended to
20 cooperate.

 With particular reference to the cross-sectional view of Figure 10, lower cap member 502 includes a cylindrical base portion 512 and a cylindrical mating extension 514. A helical

thread 516 is formed on the inner surface of base portion 512 to facilitate mounting of control mechanism 500 to a bottle or the like. Alternative mounting mechanisms may be employed to facilitate mounting of control mechanism 500 to a desired container, vessel or bottle, as will be apparent to persons skilled in the art, e.g., a bayonet lock mechanism, friction fit design or the like. Thus, the present disclosure is not limited to control mechanisms that are adapted to be joined to a container, vessel or bottle through a threading action, nor is the present disclosure limited to control mechanisms that are detachably mounted to a vessel, container or bottle. Rather, the disclosed control mechanism may be advantageously joined to such vessel, container or bottle in a substantially permanent manner; e.g., through the use of a suitable adhesive, sonic welding or the like.

With further reference to Figure 10, mating extension 514 includes a helical thread 510 formed on an external surface thereof. Helical thread 514 is adapted to cooperate with a corresponding helical thread 508 formed on the interior surface of overcap 504. Thus, the diameters of mating extension 514 and overcap member 504 are selected such that helical thread 510 effectively cooperates with helical thread 508 to facilitate movement of overcap member 504 relative to lower cap member 502, i.e., based on the rotational motion of overcap 504 relative to lower cap member 502. Typically, overcap member 504 may be unscrewed relative to lower cap member 502 through counterclockwise rotation thereof, and tightened relative to lower cap member 502 through clockwise rotation.

With reference to Figure 7, a series of ridges 517 are formed on the exterior surface of mating extension 514, particularly at the lower end thereof. Ridges 517 are typically vertically oriented and typically extend circumferentially, in a spaced side-by-side

arrangement, around mating extension 514. As noted previously, a helical thread 510 extends around mating extension 514. According to an exemplary embodiment of the present disclosure, ridges 517 circumferentially increase in height so as to substantially track helical thread 510. Thus, according to such exemplary embodiment, each ridge 517 extends

5 upwardly on mating extension 514 such that the ridge 517 ends at (or near) the lowest extremity of helical thread 510, i.e., the ridge 517 typically ends at, or immediately short of helical thread 510. In an alternative embodiment, one or more ridges 517 may extend into the space between adjacent helical thread portions. A stop 518 (see Figures 8 and 10) is advantageously formed on the interior of overcap 504, e.g., at or near the end of thread 508.

10 Stop 518 extends inwardly and typically performs three functions in combination with lower cap member 502.

First, stop 518 contacts the series of ridges 517 to provide a tactile sensation as overcap 504 is rotated relative to lower cap member 502. This tactile sensation provides advantageous tactile feedback to a user who is undertaking to “open” or “close” control

15 mechanism 500. Second, stop 518 is adapted to engage a single ridge formed near the top of the highest thread on lower cap member 502. This engagement between stop 518 and a corresponding “stop ridge” formed on cap member 502 functions to prevent overcap 504 from becoming disengaged from cap member 502, absent a level of force required to overcome such engagement. Of note, stop 518 includes an angled or tapered surface on the side

20 opposite its “engagement” side, thereby facilitating initial assembly of overcap 504 onto cap member 502. Finally, stop 518 interacts with ridges 517 such that, during use, overcap 504 is less susceptible to unintended rotational motion relative to cap member 502, e.g., when an

animal is licking ball 506, as described below. Thus, the interaction between stop 518 and the ridges formed on cap member 502 facilitates the operability and stability of control mechanism 500.

Gripping ridges 522, 524 are typically formed on the exterior of overcap 504 and cap member 502, respectively. Gripping ridges 522, 524 are circumferentially spaced around the periphery of overcap 504 and cap member 502, and are typically vertically oriented. Although the number of gripping ridges is a matter of design choice and is typically dependent, at least in part, on the diameter of a specific control mechanism, according to exemplary embodiments of the present disclosure, about six to twelve gripping ridges are typically defined on each of the overcap and cap member. An equal number of equally spaced gripping ridges are typically provided, although the disclosure is not limited to such an arrangement.

In addition to gripping ridges 522, 524, reference marker 526 is formed on the exterior surface of cap member 502, at or near the top thereof. A series of positional markers 528 are formed on the exterior of overcap 504, toward the bottom thereof. A first positional marker 528 is typically located on overcap 504 and, in one exemplary embodiment of the present disclosure, the first positional marker 528 is aligned with reference marker 526 (or in close proximity thereto) when overcap 504 is fully “tightened down” on cap member 502, i.e., control mechanism 500 is closed. The additional positional markers 528 are circumferentially spaced around the periphery of overcap 504 (see Fig. 9) and, based on alignment of such additional positional markers 528 with reference marker 526, reflect the degree to which control mechanism 500 has been opened (by rotation of overcap 504 relative to cap member 502).

In fabricating control mechanism 500, the various positional markers 528 may be designated as reflecting varying degrees of flow, whether in absolute flow terms (e.g., based on flow measurements) or in relative flow terms (e.g., big thirst/medium thirst/little thirst; big dog/little dog/puppy; wide open/medium flow/trickle; etc.). As shown in Figs. 6 and 7, the relative length of positional markers 528 may increase to reflect relative increases in the degree of flow through control mechanism 500. Other “flow-related” indicia may be incorporated with positional markers 528 to reflect relative flow, as will be apparent to persons skilled in the art. In the exemplary embodiment of Figs. 6-10, four equally spaced positional markers 528 are provided, but the present disclosure is not limited to such arrangement, as will be readily apparent to persons skilled in the art.

With particular reference to Fig. 10, ball 506 is captured between overcap 504 and cap member 502. In exemplary control mechanism 500, a beveled top surface 560 and central opening 562 are defined by overcap 502. Central opening 562 is substantially circular in geometry and is sized such that ball 506 cannot pass therethrough. Thus, in an exemplary embodiment of the present disclosure, central opening 562 may be about 0.5 to 0.75 inches in diameter, while ball 506 may have a diameter of about 0.75 to 0.9 inches. The precise dimensions of ball 506 and central opening 562 are not critical, so long as ball 506 is not permitted to pass through such opening. In the disclosed embodiment of Figures 6-10, beveled top surface 560 includes a chamfered region 564 adjacent central opening 562. Chamfered region 564 provides a smoother transition between overcap 504 and ball 506, thereby providing for more efficacious use of control mechanism 500, e.g., as a drinking aid for a pet.

Cap member 502 defines an inwardly directly conical flange 570 that supports ball 506 at the side opposite beveled top surface 560. Conical flange 570 defines an opening 572 that, in exemplary embodiments of the present disclosure, is substantially circular in geometry. The diameter of opening 572 is sized such that ball 506 is not permitted to pass through.

5 Thus, the parameters for sizing opening 572 are analogous to those applicable to central opening 562 of overcap 504, discussed above. Both beveled top surface 560 and conical flange 570 are fabricated from substantially rigid materials, e.g., appropriate plastic materials, so that the motion of ball 506 within control mechanism 500 is substantially limited to rotational motion between beveled top surface 560 and conical flange 570.

10 In use, the rotation/movement of ball 506 is generally prevented when overcap 560 is tightened relative to cap member 502. In such circumstance, beveled top surface 560 and conical flange 570 bear against ball 506 to completely restrict/block the potential fluid flow path from end 580 of control mechanism 500. Thus, at opposed sides of ball 506, a substantially circumferential bearing surface is defined between ball 506 and beveled top
15 surface 560/conical flange 570, respectively. When overcap 504 is rotated relative to cap member 502 such that beveled top surface 560 moves away from ball 506, movement of ball 506 relative to both overcap 504 and cap member 502 is permitted based on the circumferential clearance regions that are created therebetween. The relative size of such clearance regions which define a “variable flow clearance” is dependent on the degree to
20 which overcap 504 is moved away from cap member 502, i.e., the degree to which overcap 502 is rotated relative to cap member.

As overcap 504 is moved away from cap member 502, ball 506 is provided with multiple freedoms of movement: rotational, axial and limited lateral movement. The degree of axial movement permitted ball 506 is particularly dependent on the degree to which overcap 504 is moved away from cap member. Axial movement of ball 506 within the constrained space between overcap 504 and cap member 502 to permit greater fluid flow around and past ball 506 may be effected by a user of the disclosed control mechanism. Thus, for example, when control mechanism 500 is used to provide fluid refreshment to an animal or pet, e.g., a dog, cat, rodent or the like, the animal's tongue may simultaneously cause rotational movement of ball 506, axial movement of ball 506 away from overcap 504, and limited lateral movement of ball 506 within the confined region, thereby establishing a greater clearance for fluid flow around ball 506 when the dog's tongue is in contact with ball 506. When the vessel/container is inverted and the animal's tongue is moved away from ball 506, fluid flow is generally restricted or curtailed, e.g., based on the forces of gravity and fluid pressure on ball 506 bringing ball 506 into restrictive contact with overcap 504. When it is desired to positively discontinue fluid flow through control mechanism 500, overcap 502 may be rotated in the opposite direction relative to cap member 504, thereby closing off the noted clearance regions.

In circumstances where control mechanism 500 may be used to deliver fluid to an animal, e.g., a dog, cat, rodent, ferret or the like, the material of construction for ball 506 is advantageously selected to have a specific gravity that is greater than the specific gravity of the fluid to be dispensed therethrough. By employing a material having the foregoing specific gravity, operation of ball 506 is generally improved because ball 506 does not "float" relative

to the fluid and is more susceptible to rotational motion based on forces applied by the animal's tongue.

Product indicia, brand information or other relevant information may be advantageously presented on control mechanisms according to the present disclosure. Thus, with further reference to Figures 6, 7 and 9, control mechanism 500 includes product indicia 580 formed on the beveled top surface 560 of overcap 502. In the disclosed exemplary embodiment, product indicia 580 constitutes a product brand name ("Pet Top") for control mechanism 500. Product indicia may be printed, embossed, molded or otherwise applied to control mechanism 500. In the disclosed exemplary embodiment, product indicia 580 is embossed into top surface 560 in three spaced locations. According to preferred embodiments of the present disclosure, to the extent product indicia 580 are presented on surfaces associated with fluid dispensation, e.g., top surface 560 or ball 506, such product indicia 580 is advantageously formed in/on the control mechanism in a recessed (as opposed to raised) manner, thereby minimizing the potential irritation and/or annoyance that might be encountered by an animal and/or individual who is accessing fluid therethrough.

It is contemplated that different color schemes and/or colorant materials may be advantageously employed in fabricating control mechanisms according to the present disclosure. Thus, it is contemplated that overcap 504 and cap member 502 may be fabricated from a transparent and/or translucent material, and that ball 506 may include a bright and/or fluorescent colorant to increase the visual novelty of the disclosed device. Alternative aesthetic combinations may be employed to enhance the market acceptance and/or market interest in the mechanisms of the present disclosure.

Of note, control mechanisms according to the present disclosure may advantageously include a backflow valve or mechanism to prevent and/or inhibit the flow of fluid back into the associated vessel, container and/or bottle, e.g., when the vessel, container or bottle is returned to an upright (or relatively upright) orientation. The backflow valve or mechanism may be advantageously mounted in the fluid flow path within lower cap member 502 and may be mounted with respect to lower cap member 502 such that the rotational motion of ball 506 is not impeded or otherwise inhibited, and further such that the mounting of control mechanism 500 with respect to a vessel, container and/or bottle is not negatively impacted. Thus, for example, a duck bill valve or other conventional backflow valve/mechanism may be mounted to lower cap member 502 so as to extend across the internal region of control mechanism 500 and prevent and/or inhibit the flow of fluids, as noted above.

A backflow valve/mechanism may be particularly advantageous where it is desired to prevent backflow of fluids into a container, vessel or bottle that may be used by a different individual or species. Thus, in circumstances where the disclosed control mechanism is utilized to permit an animal, e.g., a dog, cat, rodent or ferret, to access fluids from a vessel, container or bottle, the inclusion of a backflow valve/mechanism may be desirable to prevent/inhibit the backflow of fluids that contain saliva of such animal. Thus, fluid remaining in the vessel, container or bottle may be subsequently accessed by an individual, with a reduced potential for the presence of animal saliva or the like.

Inclusion of a backflow valve/mechanism may permit and/or facilitate the disclosed control mechanism to be employed in the delivery of supplements and/or medicines to an animal, e.g., by positioning the supplement/medicine in the region between the backflow

valve/mechanism and the ball, and permitting the flow of fluids therethrough to deliver such supplement/medicine to the animal, while minimizing the further dilution and/or loss of such supplement/medicine within the attached vessel, container and/or bottle. The supplement/medicine may be in the form of a solid (e.g., pill or powder), liquid or slurry.

5 Thus, the disclosed control mechanism may be pre-loaded with a desirable supplement and/or medicine for an animal (or human) and may be employed for administration of such supplement/medicine, as noted herein. Alternatively, a desirable supplement and/or medicine may be introduced to the disclosed control mechanism on an as-needed or as-desired basis by the control mechanism user.

10 It is further contemplated according to the present disclosure that structure(s) may be included as part of the disclosed control mechanism to assist in assuring the integrity of the fluids to be dispensed thereby, i.e., means for ensuring product integrity, particularly when the control mechanism is secured and/or mounted to a vessel, container or bottle containing such fluid. Thus, for example, the overcap and the lower cap member may be fabricated such that
15 one or more strips of material extend therebetween, such strip(s) of material being broken when the overcap is first rotated relative to the lower cap member. The strip(s) of material may take the form of thin vertical strips that are formed during molding and/or as a post-molding operation, as will be apparent to persons skilled in the art. Similarly, means for ensuring product integrity may be provided between the disclosed control mechanism and the
20 vessel to which it is mounted. Thus, one or more strips of material may extend between the control mechanism and the vessel, container or bottle to signal/indicate product integrity, such strip(s) being broken when (and if) the control mechanism is rotated relative to such vessel,

container or bottle. In addition to friable material strips, the means for ensuring product integrity may take the form of an overwrap of plastic material (e.g., a plastic shrink-wrap) or other product packaging system that is designed to ensure product integrity, as are generally known in the art. In this way, a user can be assured that the fluid contained within the vessel, container or bottle has remained in a sealed/closed condition since initial packaging.

Turning to Figs. 11-16, a further exemplary control mechanism 600 according to the present disclosure is schematically depicted. Control mechanism 600 shares many structural and functional features with the embodiments described herein above, and such shared structural/functional features are not described in detail with respect to control mechanism 600. For example, control mechanism 600 may also be used in a host of applications, including systems wherein a fluid is to be consumed, e.g., an animal/pet drinking aid, and systems wherein a fluid is to be applied to a surface or substrate, e.g., as part of a deodorant, anti-perspirant or other fluid dispensing apparatus and/or in wetting envelopes, applying a colorant or adherent to a substrate, and the like. In view of such shared structural and functional features, the present description with respect to the embodiment of Figs. 11-16 will focus primarily on structural/functional differences relative to the embodiments previously described herein.

With initial reference to Figs. 11 and 12, control mechanism 600 includes a lower cap member 602, an overcap 604 and a ball 606. Control mechanism 600 is substantially cylindrical in shape, with a truncated, conical upper portion formed by overcap member 604 and an overall diameter that is generally defined based on the size and/or dimensions of the neck of the container, vessel or bottle with which it is intended to cooperate. With reference

to Figures 15 and 16, lower cap member 602 includes a cylindrical base portion 612 and a cylindrical mating extension 614, with a helical thread 616 formed on the inner surface of base portion 612 to facilitate mounting of control mechanism 600 to a bottle, vessel or the like. Alternative mounting mechanisms may be employed to facilitate mounting of control
5 mechanism 600 to a desired container, vessel or bottle, as will be apparent to persons skilled in the art, e.g., a bayonet lock mechanism, friction fit design, adhesive, sonic weld or the like.

With further reference to Figure 16, mating extension 614 includes first and second helical threads 610a, 610b formed on an external surface thereof. Helical threads 608a, 608b are defined on an interior wall of overcap 604. First and second helical threads 610a, 610b
10 and helical threads 608a, 608b each define “double threads,” such that when overcap 604 is mounted relative to lower cap member 602, a pair of thread engagements take place, thereby enhancing the stability of the combined structure. For example, helical threads 608a, 610a may engage each other, while simultaneously helical threads 608b, 610b engage each other, e.g., at an angular distance that is 180° removed. Thus, in an exemplary embodiment of the
15 present disclosure, first helical thread 610a is offset from second helical thread 610b by about 180° and, similarly, first helical thread 608a is angularly offset by about 180° from second helical thread 608b. First helical thread 610a and second helical thread 610b are interspersed, i.e., nested relative to each other. A similar nesting of first and second helical threads 608a, 608b is generally effected. Mating extension 614 and overcap member 604 are sized such that
20 helical threads 610a, 610b can each effectively cooperate with helical threads 608a, 608b to facilitate movement of overcap member 604 relative to lower cap member 602.

An alignment marker, e.g., alignment line 621 (see Fig. 12), may be included on overcap 604 to facilitate proper alignment between helical threads 610a, 610b and helical threads 608a, 608b. Alignment marker 621 is advantageously aligned with reference marker 626 when overcap 604 is initially brought into engagement with lower cap member 602, i.e., before relative rotation is commenced. More particularly, in an exemplary embodiment of the present disclosure, alignment line 621 is positioned adjacent the end of a helical thread formed interior to overcap 604 and is useful in positioning overcap 604 in an angular orientation relative to lower cap member 602 such that it aligns with one of the double threads formed internal to lower cap member 602. Incorporation of an alignment marker, e.g., alignment line 621, permits the user to reliably benefit from a variety of advantageous functionalities associated with proper alignment of components of the disclosed device, e.g., a full range of variable fluid flow and proper functioning of outwardly directed flow indicia, by ensuring that the double threads are properly matched as between the overcap and the lower cap member. Typically, overcap member 604 may be unscrewed relative to lower cap member 602 through counterclockwise rotation thereof, and tightened relative to lower cap member 602 through clockwise rotation.

A washer or O-ring (not pictured) may be positioned around mating extension 614 to provide enhanced sealing of overcap member 604 relative to lower cap member 602, e.g., a rubber O-ring. The washer/O-ring may be positioned below helical threads 610a, 610b, e.g., in close proximity to base portion 612 of lower cap member 602. The dimensions and properties of the washer/O-ring are generally selected such that the washer/O-ring fits snugly around mating extension 614 and under sealing compression when overcap 604 is tightened

relative to lower cap 602, i.e., the washer/O-ring effectively fills the gap between overcap 604 and lower cap 602 when control mechanism 600 is “closed”. In an alternative embodiment, a groove may be formed in mounting extension 614, e.g., adjacent base portion 612, to accommodate the disclosed washer/O-ring. The provision of a groove or other surface feature on mounting extension 614 may be desirable to enhance the security and consistent/reliable positioning of the washer/O-ring relative to lower cap member 602.

In a further exemplary embodiment, the surface around mating extension 614 below helical threads 610a, 610b, e.g., in close proximity to base portion 612 of lower cap member 602, may be raised so as to create a tight seal with overcap 604 when overcap 604 is tightened relative to lower cap 602, without the use of a washer/O-ring. As overcap 604 is tightened relative to lower cap 602, the bottom interior of overcap 604 contacts the raised surface before tightening is fully complete, and as tightening continues, overcap 604 and the raised surface seal any gaps. The raised surface may be tapered or rise gradually in slope from the point closest to the base of helical threads 610a and 610b, so as to effect minimal initial contact and allow further tightening until complete sealing is effected.

With particular reference to Figures 11-12, a series of vertically oriented ridges 617 are formed on the exterior surface of mating extension 614 in a spaced side-by-side arrangement. According to the disclosed exemplary embodiment, ridges 617 define a substantially triangular cross-section. Such triangular geometry provides an effective tactile feel for users of the disclosed control mechanism 600, while simultaneously providing effective “release” properties during typical molding procedures, i.e., in connection with fabrication of lower cap 602. Similarly, ridges 622 formed on the exterior surface of overcap 604 are in a side-by-side

space arrangement and define a substantially triangular cross-section. Typically, an equal number and spacing of ridges 617 and ridges 622 are provided on lower cap 602 and overcap 604, respectively, thereby providing a uniform look and feel to control mechanism 600 when assembled and in a “closed” configuration, e.g., as shown in Figs. 11 and 12.

5 Turning to Figs. 13 and 16, a series of spaced, vertically oriented ratchet teeth 630 are defined along a portion of the outer circumference of mounting extension 614. In an exemplary embodiment of the present disclosure, ratchet teeth 630 are formed over about 270° of the circumference of mounting extension 614, although the precise angular extent of ratchet teeth 630 is not critical to the operation and/or functionality of the disclosed control
10 mechanism. Ratchet teeth 630 interact with inwardly directed tooth 636 formed on the inner wall of overcap 604 (see Fig. 13). The intermittent contact of tooth 636 with spaced ratchet teeth 630 commences once overcap 604 has been “tightened” to the point that tooth 636 enters the same horizontal plane as ratchet teeth 630. Such intermittent contact generates a tactile and aural sensation as overcap 604 is rotated relative to lower cap 602. Of note, the height of
15 ratchet teeth 630 may be inwardly sloped/tapered, e.g., from top-to-bottom, to increase the interference contact at one end of ratchet teeth (the non-sloped/tapered end) relative to the other end. In this way, a greater interference contact may be imparted as overcap 604 is further tightened relative to lower cap 602.

 A stop tooth 632 is typically formed at one end of the angular array of ratchet teeth
20 630 (see Fig. 13). Stop tooth 632 typically defines a stop face directed toward the array of ratchet teeth. A space is typically defined between the ratchet tooth array and stop tooth 632. Such space (e.g., about 10°) provides clearance for tooth 636 to slide down/through when

overcap 604 is approaching the maximum desired open position relative to lower cap member 602, reducing the likelihood that tooth 636 will inadvertently ride over stop tooth 632. A larger angular spacing (e.g., 60-70°) is provided between stop tooth 632 and the other end of the ratchet tooth array. This greater angular spacing advantageously assures that tooth 636 is not “riding on” a ratchet tooth 630 when overcap 604 is fully tightened relative to lower cap member 602. Thus, this relatively large angular region represents the region in which tooth 636 travels when overcap 604 is in a final stage of being tightened relative to lower cap member 602.

As with previously described embodiment(s), a series of positional markers 628 may be formed on the exterior of overcap 604, e.g., toward the bottom thereof. Based on alignment of such additional positional markers 628 with reference marker 626, the degree to which control mechanism 600 has been opened (by rotation of overcap 604 relative to cap member 602) may be assessed. The relative length of positional markers 628 may increase to reflect relative increases in the degree of flow through control mechanism 600, as discussed above. In alternative embodiments of the present application, however, the ratchet teeth 630 may extend fully around the circumference of mounting extension 614, i.e. without the spacings discussed herein.

Ratchet teeth 630 are generally spaced from the top of helical threads 610a, 610b, i.e., the ratchet teeth are typically “clear” of the thread area. The gap between ratchet teeth 630 and helical threads 610a, 610b provides enhanced molding ease and reliability, and simplifies overall tool design. The positioning of ratchet teeth 630 above helical threads 610a, 610b

generally increases the overall height of mounting extension 614, e.g., relative to the exemplary embodiments disclosed above.

With particular reference to Fig. 15, ball 606 is captured between overcap 604 and lower cap member 602. A beveled top surface 660 and central opening 662 are defined by overcap 602. Central opening 662 is substantially circular in geometry and is sized such that ball 606 cannot pass therethrough. The precise dimensions of ball 606 and central opening 662 are not critical, so long as ball 606 is not permitted to pass through such opening. Cap member 602 defines an inwardly directly conical flange 670 that supports ball 606 at the side opposite beveled top surface 660. Both beveled top surface 660 and conical flange 670 are generally fabricated from substantially rigid materials, e.g., appropriate plastic materials, so that the motion of ball 606 within control mechanism 600 is substantially limited to rotational motion between beveled top surface 660 and conical flange 670.

In circumstances where control mechanism 600 may be used to deliver fluid to an animal, e.g., a dog, cat, rodent, ferret or the like, the material of construction for ball 606 is advantageously selected to have a specific gravity that is greater than the specific gravity of the fluid to be dispensed therethrough. By employing a material having the foregoing specific gravity, operation of ball 606 is generally improved because ball 606 does not “float” relative to the fluid and is more susceptible to rotational motion based on forces applied by the animal’s tongue.

As with the previously disclosed embodiments, product indicia, brand information or other relevant information may be advantageously presented on control mechanism 600 according to the present disclosure. Product indicia may be printed, embossed, molded or

otherwise applied to control mechanism 600. It is also contemplated that different color schemes and/or colorant materials may be advantageously employed in fabricating control mechanisms according to the present disclosure. Control mechanism 600 may further include a backflow valve or mechanism to prevent and/or inhibit the flow of fluid back into the associated vessel, container and/or bottle, e.g., when the vessel, container or bottle is returned to an upright (or relatively upright) orientation. For example, a duck bill valve or other conventional backflow valve/mechanism may be mounted to lower cap member 602 so as to extend across the internal region of control mechanism 600 and prevent and/or inhibit the flow of fluids, as noted above.

Turning to Figs. 17 and 18, dual fluid vessel 700 includes a first fluid region 702 and a second fluid region 704 that are separated by an internal dividing wall 706. Fluid regions 702, 704 communicate with neck or spout 708a, 708b, respectively. In the exemplary dual fluid vessel of Figs. 17 and 18, a substantially crescent-shaped outer geometry is provided, such that gripping of vessel 700 is generally facilitated. Alternative geometries and/or deployments of dividing walls may be employed, as will be readily apparent to persons skilled in the art. For example, an “hour-glass” cross-sectional geometry for vessel 700 is contemplated. As shown in Fig. 18, first neck/spout 708a receives a conventional cap 730, while exemplary control mechanism 600 is mounted to neck/spout 708b. Of course, conventional cap 730 and control mechanism 600 may be interchanged, or either may be the sole type used on both neck/spout 708a and neck/spout 708b, as desired. Moreover, alternative control mechanisms disclosed herein may be employed instead of or in addition to exemplary control mechanism 600, as will be readily apparent to persons skilled in the art.

The combination of dual fluid vessel 700, conventional cap 730 and control mechanism 700 (or dual fluid vessel 700 and multiple control mechanisms, as disclosed herein) permits a single fluid vessel to be easily and effectively used for refreshment of both pets and pet owners. Thus, for example and with reference to Fig. 18, the pet may receive fluid refreshment from fluid region 704 (through control mechanism 600), while the pet owner could access fluid refreshment from fluid region 702 (by removing conventional cap 730). The versatility and ease with which dual fluid vessel may be employed offers significant benefits to users thereof.

A further exemplary embodiment of the present disclosure is schematically depicted in Figure 19, wherein fluid control mechanism 800 incorporates an advantageous angular geometry. Fluid control mechanism 800 shares many structural and functional features with embodiments described above. However, fluid control mechanism 800 differs from previously disclosed embodiments in that overcap 804 includes an angular neck portion 875 that is defined at a location intermediate central opening 862 and lower cap member 802. Of note, upper cap 804 may be fabricated as a unitary upper cap member (not pictured), or as a two-part construction with a distinct first cap member 804a that is secured relative to a second cap member 804b. In the two-part construction, first cap member 804a may be secured to second cap member 804b through a variety of attachment means, e.g., threaded connection, sonic welding, adhesive, bayonet lock, or the like. The disclosed two-part construction facilitates assembly of internal components associated with overcap 804, as described below.

The disclosed angled neck version offers several advantageous features, including among other things: (i) an inherent ability to allow a different orientation of a bottle (not

pictured) and fluid control mechanism 800 while operating the device, (ii) an ability to allow additional fluid regulation via an extra ball as well as an optional interior flange (which would in effect capture the lower ball between itself and the lower flange), and (iii) an ability to allow fluid control mechanism 800 to be opened/closed while grasping fluid control
5 mechanism 800 further away from the distal end used by the pet or other user. Additional advantages, features and functions associated with this additional exemplary embodiment will be apparent from the detailed description which follows.

In the disclosed exemplary embodiment of Fig. 19, first cap member 804a includes a first portion that is substantially aligned with the longitudinal axis of control mechanism 800
10 and an angled that is oriented at an angle “A” relative to such longitudinal axis. Angle “A” may be selected to provide a desired orientation of central aperture 862 relative to the longitudinal axis of control mechanism 800, and may advantageously be on the order of 30° to 60°, and advantageously about 45°. Alternative angles “A” may be employed, as will be apparent to persons skilled in the art.

15 Internal to upper cap 804 are two balls, a first ball 806a that cooperates with central aperture 862 to control fluid flow therethrough, and a second ball 806b that is positioned therebelow. In an exemplary embodiment of the present disclosure, balls 806a, 806b are of similar or identical diameter, although embodiments wherein substantially different diameter balls are employed are contemplated according to the present disclosure. Balls 806a, 806b
20 interact to seal the control mechanism 800 as well as to regulate fluid flow therethrough.

Of note, lower ball 806b is generally positioned on a first mounting flange 870a that defines a central opening through which fluid passes. A second mounting flange 870b (that

also defines a central aperture for fluid passage) is optionally positioned above lower ball 806b, to further secure ball 806b relative to upper cap 804 and to provide an additional fluid regulating surface with respect to lower ball 806b, particularly when the control mechanism is inverted and/or tilted. According to an exemplary embodiment of the present disclosure, first mounting flange 870a forms part of second cap member 804b, while second mounting flange 870b is defined within first cap member 804a. In such exemplary embodiment, lower ball 806b is captured between mounting flanges 870a, 870b when cap members 804a, 804b are mounted relative to each other. Flanges 870a, 870b define a space that is dimensioned to permit movement of ball 806b (i.e., a combination of rotational and limited axial motion) relative thereto, such that, when open, fluid flow is permitted. Upper ball 806a advantageously abuts lower ball 806b, such that movement of upper ball 806a relative to upper cap 804 translates to corresponding motion of lower ball 806b, as will be apparent to persons skilled in the art. In the absence of mounting flange 870b, upper ball 806a typically functions to maintain lower ball 806b in position relative to first mounting flange 870a.

According to the alternative embodiment of Fig. 19, the lower cap 602 of the prior embodiment substantially corresponds to lower cap member 802, and the upper cap 604 of the prior embodiment corresponds in part to second cap member 804b. Thus, for example, second cap member 804b may advantageously include an internal tooth (not pictured) for interaction with ratchet teeth formed on lower cap member 802, as described with reference to prior embodiment(s). Similarly, second cap member 804b may advantageously include double-threads to interface with those on lower cap member 802.

Control mechanism 800 is opened and closed by twisting/rotating upper cap 804 relative to lower cap member 802, i.e., counter-clockwise and clockwise, respectively. When closed, the two balls 806a, 806b are in contact with each other. Rotation of the upper cap 804 relative to the lower cap member 802 forces the lower ball 806b to seat into the lower flange 870a, thereby sealing the second cap member 804b. Such rotation simultaneously seals the upper ball 806a against the upper most opening 862 of first cap member 804a. Thus, the rotation of upper cap 804 relative to lower cap member 802 applies a force between the upper ball 806a and the lower ball 806b, forcing the lower ball 806b to seal against the lower flange 870a while the upper-most flange 864 adjacent opening 862 seals against the upper ball 806a, as shown in Fig. 19. In such configuration, lower ball 806b is sealed against lower flange 870a, but slightly spaced relative to flange 870b.

Of note, in alternative embodiments of the present disclosure, relative motion between the overcap and lower cap member may be achieved (in whole or in part) through non-rotational motion. Thus, for example, axial motion may be imparted to the overcap and/or the lower cap member, such that relative motion between the structural elements is effected. Structural arrangements that permit and/or facilitate such axial motion are known in the art, e.g., concentric structures that are adapted to slide and/or translate relative to each other. In exemplary embodiments wherein non-rotational axial motion is permitted (in whole or in part), a stop position is generally defined, e.g., through an outwardly projecting rim, so as to prevent potential disengagement of the overcap from the lower cap member during use.

Although control mechanisms of the present disclosure, e.g., animal/pet drinking aids, have been described with reference to exemplary embodiments thereof, the present disclosure

is not to be limited to the specifics of the disclosed embodiments, but is to be broadly understood. For example, it is contemplated that an eyelet and cover may be secured to certain embodiments of the cap of the present disclosure, e.g., through interaction with threads formed on the exterior of the cap, thereby permitting users to affirmatively close the open end
5 of the cap (thereby potentially recessing the ball within the cap, e.g., against the bias of the compression spring or against a washer such as washer 106). It is further contemplated that for threaded embodiments of the disclosed control mechanisms and/or animal/pet drinking aids, it may be desirable to include a ridge, flange or stop on the cap at the end of the threads to provide a positive stop in connection with the screwing of the cap onto the bottle. The
10 disclosed embodiments are merely illustrative, and not limitative, of the scope of the present invention, and changes, modifications and/or variations may be utilized without departing from the spirit or scope of the present invention.
